

AIS Glass POC — Data Validation Update

Oct 6, 2026 · @vijji babu

We reconciled the proof of concept against the raw files Asahi India Glass supplied. The analysis matches their source data.

The analysis matches the client's data

Checked across all 53 branches and 2,063 products, over 70 weeks from April 2025 to July 2026, by recomputing every figure directly from the client's own files and comparing.

Figure	Client's file	Our analysis	
Units ordered	2,602,392	2,602,392	Exact
Units despatched	2,133,961	2,133,961	Exact
Order value	₹857.10Cr	₹857.11Cr	0.001%
Short units	504,052	504,052	Exact
Fill rate	82.00%	82.00%	Exact
Branch totals	all 53	all 53	Exact

The same check on the modelled slice — 2 branches and 136 products — also matches exactly on every figure.

We also confirmed the five source files are **byte-for-byte identical** to what the client delivered. Nothing was edited to make the numbers work.

Three issues found during the check, all fixed

Order value was overstated by ₹2.92Cr (0.34%). Orders are grouped into weekly buckets, and we were storing a plain average of the prices in each bucket, then applying it to the whole quantity. Where a bucket holds more than one price and the cheaper lines carry more units, that overstates the value. 19,359 of 582,324 buckets hold more than one price. Now weighted by quantity, so the figure reproduces the line-by-line total.

246 units were wrongly counted as short. 44 order lines have a blank despatch quantity. We were reading blank as zero despatched, which turned the whole order into a shortfall. Blank means *not recorded*, which is not the same as *nothing shipped*. Those lines are now excluded from the shortfall and counted separately.

2,641 units were missing from five charts. The charts that break demand down by product attribute — glass type, value class, vehicle category — were discarding any order line whose product is not in the client's catalogue. Those units still appeared in the headline total, so the bars did not add up to the tile, with nothing on screen explaining the difference. They now appear under a labelled **"Not in product master"** category.

All three were corrected and every figure re-verified. None of them affected the forecasts: the models predict ordered quantity, which was correct throughout.

One item needs the client's input

Two product codes appear in their order file but are missing from their own product catalogue.

Product code	Units ordered	Branches ordering it
FG.J90.LFH.SCSB1B0000	2,605	44 of 53
FG.KSM.BCK.G00320A200	36	28 of 53

We can count the units, but with no catalogue entry we cannot say what glass type, value class or vehicle category they belong to. Our charts now show them under a "Not in product master" category, so every total adds up and the gap is visible rather than hidden. What we cannot do is classify them — only the client can supply the missing records.

It is 0.1% of demand, and nothing is miscalculated. The point worth raising is that one of these is a mainstream product, ordered by 44 of their 53 branches, that is absent from their own master data. That is likely causing them problems in their own systems too, not only in ours.

Where this leaves us

The analysis is sound and ready to present. Every headline figure traces back to the client's own files, and the two issues we found were in our processing, not in their data.

Two things need the client's input:

- ☐ Ask the client for the two missing product records, and confirm whether a blank despatch quantity means "not shipped" or "not recorded" — we have assumed the latter
- ☐ Agree whether the forecasting scope should widen beyond the 2-branch, 136-product pilot

One thing worth saying plainly if it comes up: the forecasting still covers 2 branches and 136 products, which is about 9% of their network by volume. Overall Analysis now describes all 53 branches, but the models have not been trained beyond the pilot slice.
